

# Word embeddings

Mannu Malhotra

# Agenda

- Introduction to text classification and the dataset.
- Data representation: Count vectors
- Hands-on on count vectors.
- Data representation: TFIDF
- Hands-on TFIDF.
- Data representation: “Word embeddings” the holy grail.
  - Introduction to word embeddings
  - Learning word embeddings
- Hands-on on word embeddings
- Implement skip gram

# A problem on text classification!

-

# Representation of text data

- Counter vectorization
- TF-IDF vectorization
- Word embeddings

# Count vectorization / One hot encoding

Rome =  $[1, 0, 0, 0, 0, 0, \dots, 0]$

Paris =  $[0, 1, 0, 0, 0, 0, \dots, 0]$

Italy =  $[0, 0, 1, 0, 0, 0, \dots, 0]$

France =  $[0, 0, 0, 1, 0, 0, \dots, 0]$

word V

Counter vectorization:

Hands on

# Count vectors

- What is wrong?
  - Some words are useless (stopwords).
  - How relevant a term is to a document?

# TF-IDF

- TF: Term frequency
  - IDF: Inverse document frequency.
- 
- Importance of a term  $\propto$  frequency of the term in a document.
  - Importance of a term  $1 / \propto$  frequency of the term in all the document

$$TF(i, j) = \frac{\text{Term } i \text{ frequency in document } j}{\text{Total words in document } j}$$

$$IDF(i) = \log_2 \left( \frac{\text{Total documents}}{\text{documents with term } i} \right)$$

TFIDF

Hands on

# Word embeddings:

- What is the problem with existing representations:
  - Sparse representation.
  - No similarity between words.
    - Train: The movie is awesome; Test: The movie is good.
  - No featurized representation.

# Word embeddings:

- What are word embeddings:
  - Featurized representation of words.

## Featurized representation: word embedding

	Man (5391)	Woman (9853)	King (4914)	Queen (7157)	Apple (456)	Orange (6257)
Gender	-1	1	-0.95	0.97	0.00	0.01
Royal	0.01	0.02	<u>0.93</u>	<u>0.95</u>	-0.01	0.00
Age	0.03	0.02	0.7	0.69	0.03	-0.02
Food	0.04	0.01	0.02	0.01	0.95	0.97

# Word Embeddings

- What are word embeddings?
  - A matrix of size  $|V| * \text{num\_of\_features}$
  - Embedding matrix, one-hot vector, embedding vector.
  - Embedding vector = Embedding matrix (dot product) one-hot vector

# Visualizing Words Embeddings:

- If we visualize after dimension reduction:

# Words Embeddings:

- Train: The movie is awesome; Test: The movie is good.
- Embeddings:
  - Awesome: [.54, .02, .93, .80, .....]
  - Good: [.50, .05, .90, .85, ....]

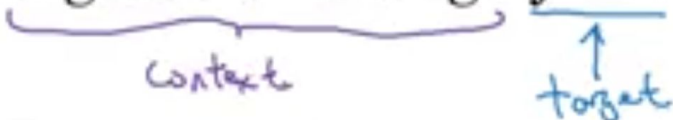

# Word Embeddings: How do we use them

- Transfer learning:
  - Download pre trained word embeddings.
  - Transfer embeddings on the new task with your dataset.

# Word Embeddings: How to learn embeddings?

- How do we find the feature representation scores?
- “A word is known by the company it keeps.”
- Target/context pairs:

I want a glass of orange juice to go along with my cereal.

The diagram illustrates a target/context pair from the sentence "I want a glass of orange juice to go along with my cereal." The words "a glass of orange" are grouped by a purple bracket underneath and labeled "context" in blue. The word "juice" is underlined in blue, and a blue arrow points up to it from the label "target" in blue.

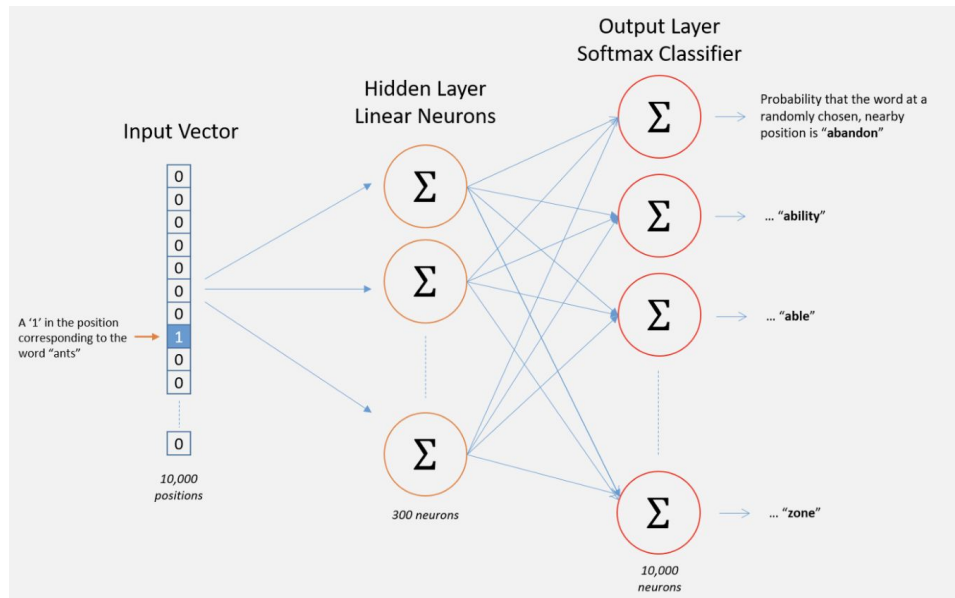

# Word embeddings: skip gram

- Step 1: Create source-target pairs.

Source Text	Training Samples						
<table><tr><td>The</td><td>quick</td><td>brown</td></tr></table> fox jumps over the lazy dog. ➡	The	quick	brown	(the, quick) (the, brown)			
The	quick	brown					
<table><tr><td>The</td><td>quick</td><td>brown</td><td>fox</td></tr></table> jumps over the lazy dog. ➡	The	quick	brown	fox	(quick, the) (quick, brown) (quick, fox)		
The	quick	brown	fox				
<table><tr><td>The</td><td>quick</td><td>brown</td><td>fox</td><td>jumps</td></tr></table> over the lazy dog. ➡	The	quick	brown	fox	jumps	(brown, the) (brown, quick) (brown, fox) (brown, jumps)	
The	quick	brown	fox	jumps			
<table><tr><td>The</td><td>quick</td><td>brown</td><td>fox</td><td>jumps</td><td>over</td></tr></table> the lazy dog. ➡	The	quick	brown	fox	jumps	over	(fox, quick) (fox, brown) (fox, jumps) (fox, over)
The	quick	brown	fox	jumps	over		

# Word embeddings: skip gram

- Step 2: Convert to it one hot encoding.
- Step 3: Feed it to two layers NN: A multiclass classification problem.
  - Hidden layer: 300 neurons
  - Softmax layer:  $|V|$  neurons
- Step 4: Train the NN with source-target pairs.
  - Intuition: Ask the model to predict target given source word.
- Wait? What is 300 here?
  - Features: latent variables

# Word embeddings

- Weights of the hidden layer:  $|v| * 300$
- Voilà!! We got the embeddings matrix.

# Word Embeddings: Problem with Skip Gram

- Softmax for  $|v|$  units can be really slow!
- Too many weights:
  - $|V| = 10,000$ , latent variables = 300.
  - # of weights = 3 million weights.
- Gradient descent can be really slow.
  - # of training samples are in billions.
  - Expensive softmax operations.

$$p(w_O|w_I) = \frac{\exp(v'_{w_O}{}^\top v_{w_I})}{\sum_{w=1}^W \exp(v'_w{}^\top v_{w_I})}$$

# Word Embeddings: Negative sampling

- Idea: Divide 10000 class softmax to 10000 binary classification problem.
- Step 1: Create 1 positive + k negative samples.

I want a glass of orange juice to go along with my cereal.

<u>context</u>	<u>word</u>	<u>target?</u>
<u>orange</u>	<u>juice</u>	1
<u>orange</u>	<u>king</u>	0
orange	book	0
orange	the	0
orange	<u>of</u>	0

- Step 2: For every pair train K+1 binary classifier.

# Word embeddings

- But wait the dimension of the data representation increased.
- How do we input it to the model now?
- Two ways:
  - Mean embeddings.
  - IDF embeddings.

$$X_{\text{mean-embeddings}} = \frac{1}{|\text{document}|} \sum_{\text{word}}^{\text{document}} W2V[\text{word}]$$

$$X_{\text{TFIDF-embeddings}} = \frac{1}{|\text{document}|} \sum_{\text{word}}^{\text{document}} W2V[\text{word}] * IDF[\text{word}]$$

- Which one to use when?
  - Mean: Good for documents with high intra document similarity and low inter document similarity.
  - IDF: Good for documents with low intra document similarity and high inter document similarity.
